# COMMERCIAL REFRIGERATED BEVERAGE VENDING MACHINE OUTDOOR LOCATION AND ELEVATED (90°F) OUTDOOR TEMPERATURE ANALYSIS

Max Wei and Jeffery B. Greenblatt

July 8, 14

## Summary

The purpose of this LBNL report is to document two findings: (1) the estimated fraction of beverage vending machines that are outdoors; and (2) the number of 90°F or hotter days that the overall population of BVM experiences in the course of an average year in the U.S. Based on a sampling of over 1000 BVMs located on college campuses around the country, we estimate that outdoor BVMs constitute 16% or less of the overall BVM population. We also find that the number of days hotter than 90°F for the overall population of BVM is very small (1.3%). The analysis is based on three years of annual cooling degree data (CDD) for 56 cities across the country.

## Beverage Vending Machine Sampling from U.S. Campuses

The first question to be addressed is the number of BVM that are installed outdoors.

BVM are commonly found in factories, colleges, schools, hotels, and hospitals. Intuitively, we might expect that the bulk of BVMs are found indoors for a multitude of reasons: less risk of vandalism and theft, less maintenance requirements due to a more controlled environment, longer machine lifetimes, and ease of customer access.

Given the funding constraints of this work and the desire to obtain a preliminary result without a large survey or extensive market research, a web search was conducted for BVM locations. BVM locations and types of vending machines were found for six colleges and universities around the country. This data was freely available on the web as many colleges and universities offer information on facilities and/ or auxiliary dining services for their students and staff. It was also felt that campuses and large campuses in particular are fairly representative of the general BVM population since they have a mix of building types that mirror up some of the major markets for BVM above. Campuses typically have many office buildings, laboratory buildings that could be a proxy for small factories or industrial sites, parking facilities, residence buildings that mimic commercial lodging facilities, sports facilities, and medical facilities. On the other hand, colleges and universities might have a larger prevalence of outdoor BVM since they are generally in environments where people are circulating around and where overall security may be higher than in an average setting.

Results for this sampling of campus BVM are summarized in Table 1 and raw data is provided in the Appendix. Out of a total sample of 1106 vending machines, about two-thirds are found to be beverage vending machines. Of these, on average 15.5% are located outdoors. This data set samples from a range of states in the East, Midwest and Western U.S. and draw from both urban and suburban locations. Urban locations would be expected to have more indoor BVM. However, the bulk of data is from three large universities in relatively warm weather locations (University of North Carolina-Charlotte, UCLA, and University of Texas-Austin). This data set may thus skew the estimate of outdoor vending machines to a

higher percentage, so the true number may be slightly lower than 15%. (The three large campuses have 17.7% of their BVM located outdoors, so perhaps an upper limit for outdoor BVM is 20%). Nonetheless, we take the average percentage of outdoor vending machines at 16% for the 90°F analysis below. We take the total number of BVM in the U.S. at two million units based on data from the 2009 Final Rule (Federal Register, Vol. 74, No. 167, pp. 44914-44968) extrapolated to 2014, and assume that 16% or 320,000 of these units are outdoors (Table 2).

Table 1. Beverage vending machine location data based on sampling from U.S. colleges and universities. Note that the three large universities are all in warmer weather locations, so this estimate might be skewed to higher percentage of outdoor machines.

| University or College | Location | Total VM | BVM | Pct. BVM | Outdoor BVM | Pct. Outdoor |
|---|---|---|---|---|---|---|
| **UNCC** | N.Carolina | 189 | 126 | 67% | 24 | 19% |
| **UCLA** | Los Angeles | 350 | 199 | *57%* | 44 | 22% |
| **UT-Austin** | Texas | 401 | 298 | 74% | 42 | 14% |
| **Columbia College** | Chicago | 57 | 30 | 53% | 0 | 0% |
| **Johnson Comm. College** | Kansas | 67 | 38 | 57% | 0 | 0% |
| **Miami University** | Ohio | 42 | 20 | 48% | 0 | 0% |
| **Average** | | 1106 | 711 | 64% | 110 | **15.5%** |

*Note: UCLA % of BVM was not available and is assumed to be 57%, or the median value of the other colleges. (VM= vending machines; BVM = beverage vending machines).*

Table 2. Assumptions for number of BVM in U.S. and outdoor fraction based on Table 1.

| Total number of BVM | Outdoor Fraction | Outdoor BVM |
|---|---|---|
| 2,000,000 | 16% | 320,000 |

**Elevated (90°F) Outdoor Temperature Analysis**

CDD (90°F) is defined as the number of cooling degree days above 90°F for a particular location. For example, if the outside temperature was 2 degrees above the base temperature of 90°F for 2 days, there would be a total of 4 cooling degree days over that period. Note that there is a time dependence that is subsumed in this definition since temperatures in reality vary throughout the day. Moreover, a quoted CDD (90°F) is non-unique in the sense that the same example above could also have 4 cooling degree days over 2 days if one day had an average temperature of 94 degrees and the other day had temperatures that were strictly below 90 degrees. To the extent that the energy versus temperature response of cooling appliances can be nonlinear, the cooling energy requirement for the two cases above may not identical. Still, the CDD concept is helpful to simplify historical weather data, to provide useful comparisons between two different climate zones, and to normalize end use appliance energy consumption. A map of climate zones in the U.S. is shown in Figure 1. Note that the color contrast in this plot is driven by HDD and not CDD and that the "very hot" regions of the country are primarily localized in the Deep South and desert southwest.

A summary of the approach for estimating the fraction of 90°F days for BVM across the U.S. is shown in Table 3. The main idea is to pull city level data from each state as a proxy for the climate zone in that state and to estimate the number of 90°F days for each city from historical CDD data referenced to the base 90°F temperature.

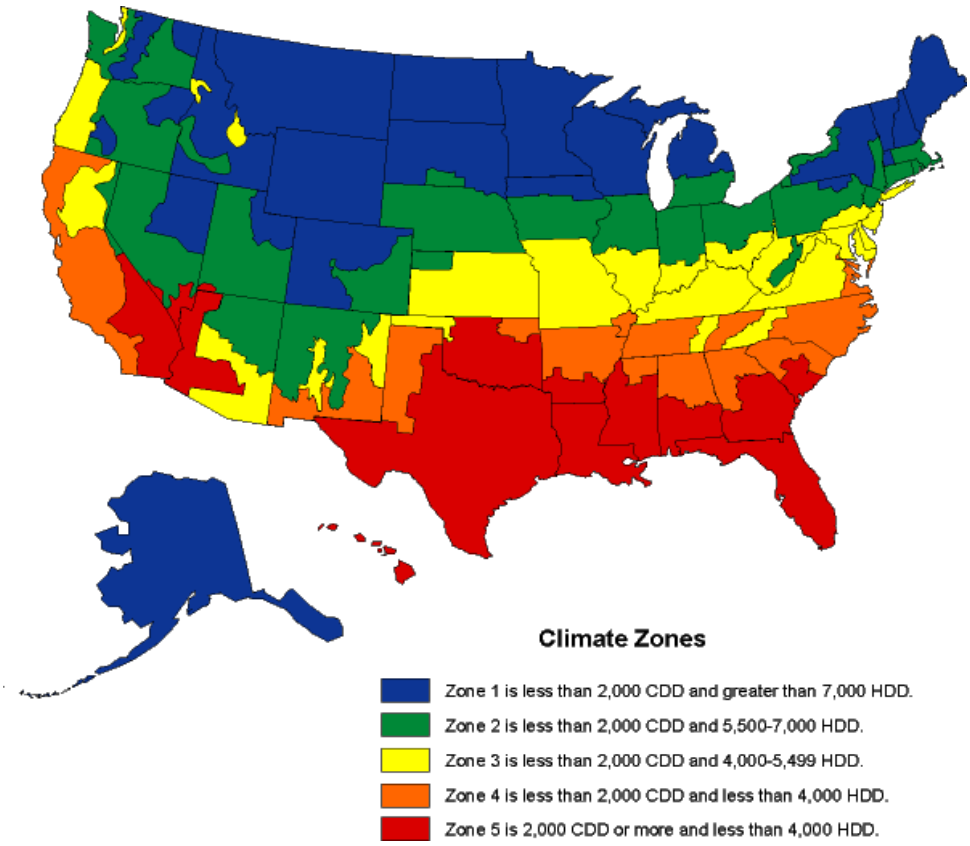

Figure 1. Climate zones for the U.S. (http://www.eia.gov/emeu/recs/origin/climzone.gif; Accessed 15 November 2013).

The first step from Table 3 below is to estimate the total number and number of outdoor BVMs by state. We assume a state population-weighted fraction of BVMs for each state and that 16% of BVMs are outdoors as in Tables 1 and 2 above. CDD data is pulled for the city with the highest population in each state from the www.degreedays.net website. An average of three historical years is taken (2010-2013). Several large states used multiple city data (Arizona, California, Missouri, Texas, and Washington) and an appropriate population weighting of CDD for those states. For example, Texas includes a population-weighted CDD for Houston, San Antonio and Dallas, the largest three cities in the state and California takes a population-weighted CDD for Central Valley and coastal cities. Other large states are represented by one city. For example greater than 80% of population of New York State is in the New York City area, and similarly large fractions of respective state population reside near Philadelphia, Pennsylvania and Las Vegas, Nevada.

The number of days above 90°F is estimated as follows. Any day with CDD(90°F) $\geq 1$ is counted as one day but any day with CDD(90°F) $< 1$ is counted as a fractional day equal to its CDD value. For example, a day with CDD=2 is counted as one day but a CDD=0.2 is counted as only 1/5 of a day. Note that a finer grained analysis would look at the baseline energy consumption at operating temperatures below 90°F

and keep a tally and running sum of the increase in energy pegged to each increasing increment in CDD value. This would essentially calculate how much increase in BVM energy is due to hot summer days. As one indicator of how many "really hot days" there are in the course of a typical year, the average CDD value for 45/50 states is less than or equal to 1.3. This means that for approximately half of the "hot" days in these states, the average daily temperature is within a degree or two of 90°F. The five states with higher average CDD values are Arizona, Kansas, Oklahoma, Nevada, and Texas, which together constitute about 13.3% of the U.S. population. We thus did not find an overwhelming reason to justify doing this more fine-grained detailed analysis, although it would be a relatively straightforward extension of this work.

Finally, the fraction of days greater than 90°F for the overall population of BVM for a given state can be readily calculated as

$$[\text{Outdoor BVM Pop.} * N_i] / [\text{Total BVM Pop.} * 365.2]$$

where $N_i$ is the number of days above 90°F for each state.

Table 3. Summary for estimating the fraction of 90°F days for BVM across the U.S.

| Step | Notes & Assumptions | Data |
|---|---|---|
| **1. Estimate number of total and outdoor BVM by state** | Assume state-weighted population for number of BVM and that 16% of BVM are outdoors | State population data from Wikipedia |
| **2. Pull CDD(90°F) for the highest population city in each state** | Several large states used multiple city data (Arizona, California, Missouri, Texas, Washington)<br><br>Other large states are represented by 1 city (For example greater than 80% of population of New York is in New York City area, and similarly for Pennsylvani/Philadelphia and Nevada/Las Vegas) | CDD data: http://www.degreedays.net/<br><br>City population data from http://www.citypopulation.de/ and other websites. |
| **3. Find number of days above 90°F for each city, Ni** | Sum (Number of days with CDD ≥ 1, Sum of CDD values for days with CDD < 1) from #2 above<br><br>For example a day with CDD=2 is counted as one day but a day with CDD=0.2 is counted as only 1/5 of a day | |
| **4. Calculate fraction of days greater than 90°F for each state** | Calculated using following expression: [ Outdoor BVM Pop. * Ni] / [Total BVM Pop. * 365.2] | |

## Results and Discussion

A summary table of results is shown in Table 4 below. We find that only 1.3% of "beverage machine days" are above 90°F where a single BVM is defined to have 365.2 beverage machine days each year. As noted above, only a few states have greater than 2% of beverage machine days above 90°F (Arizona,

Nevada, Texas, Oklahoma, and Kansas). Even if the number of 90-degree days were to double in the future due to climate change, the fraction of BVM days above 90°F would still be less than a few percent. We conclude that the amount of time spent at 90°F or above outdoors is low.

Table 4. Estimation of total BVM-days above 90F by state. Each BVM has 365.2 machine days per year.
